Output	5
Conclusion	6

Theory (Logic)

This is a C++ program that shows how to create and use a class. First, we write `#include<iostream>` which is a header file library that lets us work with input and output objects, and `<string>` to use string variables. Then we create a class called `MyClass`. A class is a user-defined data type that we can use in our program, and it works as an object constructor. It has two public variables: an integer variable called `myNum`, and a string variable called `myString`. Public means they can be accessed from outside the class. Then in the `main()` function, we create an object called `myObj` of the class `MyClass`. This object is used to access the variables inside the class. We give `myObj.myNum` the value 1, and `myObj.myString` the value "code". Finally, we use `cout` to print these values.

Pseudo Code

Step 1: Include <iostream>

Step 2: include <string>

Step 3: Use the standard namespace

Step 4: Create a class called MyClass. Class has two variables, integer: myNum and string: myString

Step 5: Start the main function.

Step 6: Create an object of MyClass called myObj.

Step 7: Set myObj.myNum = 1.

Step 8: Set myObj.myString = "code"

Step 9: Print myObj.myNum

Step 10: Print myObj.myString

Step 11: End the main function

Program Code

```
#include<iostream>
#include<string>
using namespace std;
class MyClass
{
    public:
        int myNum;
        string myString;
};

int main()
{
    MyClass myObj;
    myObj.myNum = 1;
    myObj.myString = "code";
    cout << myObj.myNum << "\n";
    cout << myObj.myString;
    return 0;
}
```

Output

```
1  
code
```

Conclusion

Code is run successfully, required output is received.
