Theory(Logic)

This C++ program demonstrates how to pass and return objects to and from a function. Firstly a class named student is created with public variable marks, which stores a student's score. The constructor of the class takes a double value to initialize the marks field when a student object is created. A separate function named average_marks is created to take two student objects as input. Then the average is calculated by adding the marks of both students and dividing by two. This function returns average. In the main() function, two student objects are created having marks 66 and 50 respectively. The average_marks function is then called with these objects, and the result is stored in an integer variable avg. Finally, the average is printed using cout.

Pseudo Code

Step 1: Include <iostream>

Step 2: Use the standard namespace

Step 3: Create class named student:

Create variable marks

Constructor(m):

marks = m

Step 4: Create a function called average_marks(student1, student2):

Return(student1.marks + student2.marks) / 2

Step 5: Start main function

Create object student1 with marks 66

Create object student2 with marks 50

Call average_marks with student1 and student2, store result in avg

Print average marks

Step 6: End main function

Program Code

```
#include<iostream>
using namespace std;
class student
{
    public:
    double marks;
    student(double m)
    {
        marks=m;
    }
};
double average_marks(student s1,student s2)
{
    return(s1.marks+s2.marks)/2;
}

int main()
{
    student student1(66),student2(50);
    int avg= average_marks(student1, student2);
    cout<<"average marks= "<<avg<<"\n";
    return 0;
}
```

Output

```
average marks= 58
```

Conclusion

Code is run successfully, required output is received.
