**Academic Year:** 2025-26

**Year:** Second Year

**Semester:** II

**PRN No.:** 1012411011

**Name:** Riddhee Kulkarni

**Subject:** Python Programming

**Assignment No.:** 21

**Date:** 16/03/2026

## Lab Assignment: 21

**Aim:**

To write a Python program to check whether a given character is present in a string and print the index at which it occurs.

**Objective:**

- To understand string searching in Python.
- To check whether a character exists in a string using the `in` operator.
- To find the position of the character using the `index()` method.

**Theory:**

A **string** is a sequence of characters in Python. Python provides several built-in methods to manipulate and search strings.

- The **`in` operator** is used to check whether a specific character or substring exists in a string. It returns `True` if present, otherwise `False`.
- The **`index()` method** returns the **first occurrence** of the specified character in the string.
- If the character is not present, `index()` normally raises an error, but using it after checking with `in` prevents the error.

**Example:**

If the string is **"hello"** and the character is **"l"**, the output will be **2**, because indexing in Python starts from **0**.

**Algorithm:**

1. Start the program.
2. Accept a string from the user.
3. Accept a character to search in the string.
4. Check if the character exists in the string using `in`.
5. If present, use `index()` to find its position.
6. Print the index of the character.
7. If not present, print that the character is not found.
8. Stop the program.

Pseudo Code:

START

INPUT string

INPUT character

IF character in string

    index = string.index(character)

    PRINT index

ELSE

    PRINT "Character not present"

END

Code:

```
string = input("Enter a string: ")
ch = input("Enter a character to search: ")

if ch in string:
    print("Character found at index:", string.index(ch))
else:
    print("Character not present in the string")
```

Output:

```
Enter a string: helloworld
Enter a character to search: o
Character found at index: 4
```

**Conclusion:**

Thus, the Python program was successfully implemented to check whether a character exists in a string and to display the **index of its first occurrence** if it is present.
